#### SUBJECTIVE

and I saw this patient at where she was admitted for fever and chills, rash and elevated blood pressure. She was in the hospital for approximately one week. She had a very extensive workup for the etiology of her hypertension given her unusual clinical presentation. Tests were done for coarctation, renal artery stenosis, pheochromocytoma, Cushing's syndrome. All of these tests were negative. Later during the admission, it was found out that the patient was taking Metabolife. This contains an ephedrine derivative and has been known to elevate blood pressure. Because of all the negative diagnostic tests, the etiology for her hypertension was either new onset essential hypertension or secondary to the Metabolife. Her other febrile illness was probably a co-existent condition. She was discharged on labetalol 200 mg b.i.d. and amlodipine 10 mg q.d. has been taking her blood pressure regularly at home. Because the blood pressure has dropped somewhat, she is now on 400 mg b.i.d. She feels great and nearly back to baseline.

Her echocardiogram was normal.

#### OBJECTIVE

She appears well today. Blood pressure is 110/74. Heart rate is 80 and regular. Weight is 166 % pounds. She has no JVD. Her lungs are clear to auscultation. Cardiac exam reveals a regular rate and rhythm, normal  $S_1$ ,  $S_2$ . She had no lower extremity edema.

### ASSESSMENT

Recent onset hypertension.

#### PLAN

I have instructed her to continue to checking her blood pressure at home. If it is consistently low, she can decrease the labetalol to 200 b.i.d. If then it still remains consistently low, she can stop it. If her hypertension was induced by Metabolife, her blood pressure should return to normal. If, however, she has developed essential hypertension, she will need to be on chronic antihypertensive medications. She is following with Dr. next week and I would like to see her back in approximately 4-6 weeks.
